

USER HANDBOOK

Wasnie

Functional documentation for the commission calculation and settlement platform: the scope of the calculation engine, the boundaries of the product, and the prescribed configuration procedure.

INTENDED READERSHIP

Administrative users and finance teams responsible for configuring variable compensation plans.

FUNCTIONAL SCOPE

Plans · Calculation rules · Quotas ·
Settlement cycles · Commission recovery (clawback)

CONTENTS

Document structure

This handbook follows the platform's customary operating sequence: it first describes the configuration of the compensation structure (payees, plans and rules), and then the processing of transactions and the settlement of the resulting amounts. Each section delimits the implemented behaviour, the current limitations, and the applicable calculations, supported by verified numerical examples.

1	The functional model on a single page	How the components of the system relate
2	Configuration sequence	Initial implementation procedure
3	Payees	Parties eligible for compensation
4	Plans and calculation rules	How a commission is defined
5	Rate tables	Flat, tiered and attainment-based
6	Quota accelerator	Treatment of attainment above target
7	Quota attainment	Measurement methodology
8	Quotas	Targets by payee and period
9	Transactions	Sales admitted by the engine
10	Measurement period and settlement period	Independent calendars
11	Settlement cycles (pay runs) and payments	Closing and settling a period
12	End-to-end traceability of a sale	One transaction, the complete path
13	Functionality not implemented	Explicit delimitation of scope
14	Material behaviours of the engine	Verified calculation criteria
15	Commission recovery (clawback)	Correcting a commission already settled
16	Termination management and settlement of outstanding accounts	Closing balances of departed payees
17	Account statement (ledger)	Balance and movements by payee
18	Permissions and roles	Authority matrix by profile
19	HubSpot integration	Connection and scope of synchronisation

DOCUMENT CONVENTIONS

Panels headed **System behaviour** describe implemented functionality; panels headed **Operational consideration** identify criteria that determine the outcome of a calculation; panels headed **Functionality not implemented** expressly delimit the scope of the product.

SECTION 1

The functional model on a single page

The platform is organised into two distinct domains. In the first, the compensation structure is configured, at a frequency determined by the plan itself; in the second, the engine processes the sales received and converts them into settleable amounts.

The two domains of the model

- **Configuration.** Definition of the plan, its rules, the assignments and the quotas. Performed once per compensation period or campaign.
- **Processing.** Sales enter the system, generate commission credits, are aggregated into payments, and a settlement cycle closes the period.

Relationships between periods

RELATIONSHIP	APPLICABLE CRITERION
Assignment ↔ Plan	Exact equality: the assignment period must be identical to that of the plan.
Quota ⊆ Plan	Containment: the quota period may be shorter, but must fall entirely within that of the plan.
Settlement cycle ↔ Quota	No relationship: settlement may be performed on a calendar other than the measurement calendar.

This asymmetry is what permits monthly quotas to be configured within a quarterly plan: the quota period may be shorter than the plan, whereas the assignment period may not.

SECTION 2

Configuration sequence

The platform guides the user through its initial screens in the sequence set out below. This order should be observed during initial implementation, as each step is a prerequisite for the next.

01	Payees	Registration of the individuals eligible for variable compensation.
02	Plan	The governing container, with its effective period and settlement currency.
03	Rules	The criteria by which the commission amount is determined.
04	Assignment	The link between payee and plan.
05	Quota	Required solely for attainment-based rules.
06	Transactions	Received from the CRM, by spreadsheet import, or by manual entry.
07	Settlement cycle	Processing of the period for all assigned payees.

SECTION 3

Payees

A payee is any party eligible to earn commission under a compensation plan in force.

Registration procedure

Registration is performed under *People* → *New person*. Full name and employee code are mandatory and cannot be disabled. All remaining attributes — email address, start date, role, reporting manager, employment type and location — are configured per organisation under *Settings* → *Required fields*.

IN THE INTERFACE

The required-fields screen lists each configurable attribute with a required or optional selector. Both the manual entry form and the import wizard apply that same configuration, which guarantees consistency between the two procedures.

OPERATIONAL CONSIDERATION

The start date is informational only and takes no part in any commission calculation.

SECTION 4

Plans and calculation rules

A plan is a governing container defined by its name, its effective period and its settlement currency. It comprises one or more calculation rules. Each rule determines independently whether it applies and what amount it generates: a sale that satisfies three rules produces three separate commission credits.

Configuration is performed under *Plans* → *New plan*, with rules added thereafter. Each rule comprises four elements.

4.1 Trigger: condition of application

Either all transactions may be selected, or a set of conditions combined by means of AND / OR operators.

SYSTEM BEHAVIOUR

The condition field is selected from a closed catalogue maintained by the calculation engine itself and does not accept free text. Only attributes that the engine actually evaluates can therefore be selected. The eight available fields are: transaction amount, date, quantity, source, currency, product reference (SKU), product name and category.

SYSTEM BEHAVIOUR

Operators are derived from the data type of the selected field, so the interface never offers an operator the engine would not evaluate. Text fields support equality, inequality, membership and exclusion with respect to a set; numeric and date fields support ordering comparisons. For category, the value is likewise selected from the categories registered by the organisation, with an explicit option for entering an alternative value, which prevents a transcription error from producing an inapplicable rule.

The rule is validated server-side on save: a rule that references an unknown field, applies an operator incompatible with the data type, or uses a membership operator without an associated set, is rejected rather than stored silently.

4.2 Measure: the reference magnitude

SYSTEM BEHAVIOUR

Two measures are available: **Revenue**, which takes the amount of the sale, and **Units**, which takes the quantity. Unit-based measurement supports a flat rate table only; the interface disables the remaining options and applies the flat table automatically.

4.3 Rate table

See Section 5.

4.4 Modifier, cap and floor

Once the rate table has been applied, adjustments are executed in the following invariable sequence: modifier, cap, floor.

OPERATIONAL CONSIDERATION

The three modifier types — accelerator, multiplier and spiff — currently exhibit identical behaviour: they multiply the commission amount by a given factor. The designation is a descriptive label with no functional effect. To apply a reduction, a factor below 1.0 must be used.

OPERATIONAL CONSIDERATION

The cap always applies per transaction. The form offers that option only and selects it by default. The floor operates by raising the commission amount to the configured minimum.

SECTION 4.5

Plan and assignment lifecycle

OPERATIONAL CONSIDERATION

Archiving a plan deactivates its assignments. In the same operation, all active assignments of the plan move to a deactivated state, so the plan is excluded from processing and from listings of eligible outstanding items.

SYSTEM BEHAVIOUR

A payee may be assigned to several active plans concurrently — for example, a base plan and a supplementary plan. When a sale attributed to that payee is processed, it is credited to each applicable plan rather than to one alone: the system records one credit per plan.

SYSTEM BEHAVIOUR

Where genuine attribution ambiguity arises — a payee with two or more eligible plans and no plan specified — resolution rests with the administrator. Manual entry requires the plan to be selected explicitly. Spreadsheet import and CRM synchronisation, in which no operator is present at the moment of loading, raise a visible error rather than applying an inference: the transaction remains pending and uncredited, and is listed in the panel's items-requiring-attention indicator under ambiguous attribution, grouped by payee. Resolution consists of deactivating the assignment that should not apply.

SECTION 5

Rate tables

The system supports three rate table types, all of which are selectable in the rule definition.

5.1 Flat rate

A single rate applied to the entire calculation base.

WORKED EXAMPLE

Flat rate of 10% on a sale of €50,000.00 → €5,000.00

5.2 Tiered rate on absolute amounts, calculated marginally

Each tier is defined by a lower bound, an upper bound and a rate, expressed as absolute monetary amounts rather than percentages. The calculation is marginal: the rate of each tier applies solely to the portion of the base falling within that band.

WORKED EXAMPLE — A SALE OF €800.00

Tier	0 – 500	→	5% on 500.00 =	25.00
Tier	500 +	→	10% on 300.00 =	30.00
				55.00

The result is not €80.00, which would correspond to applying a single rate located by tier.

OPERATIONAL CONSIDERATION

Tiered calculation resets on every transaction: it starts from zero for each sale and does not consult the period's accumulated amounts. A sale of €800.00 earns €55.00, whereas two sales of €400.00 earn €20.00 + €20.00 = €40.00. To configure tiers that accumulate over a period, the attainment-based table with quota accelerator must be used, not the tiered table.

5.3 Attainment-based rate, expressed as fractions of quota

Each tier is defined as a fraction of the quota, where 1.0 equals 100% of target. Those fractions are multiplied by the quota target to obtain the corresponding absolute amounts. This type requires a quota to exist for the payee and plan combination. Its behaviour depends entirely on the setting that splits commission at the quota boundary, described in the following section.

SECTION 6

Quota accelerator

This setting determines the treatment of attainment above target and has the greatest bearing on the resulting amount. It is shown for attainment-based rate tables only.

For illustration, consider an accelerator of 8.2% up to quota and 9.2% above quota, with a quota of 48,000.00 and revenue of 50,000.00.

Setting enabled: acceleration limited to the excess

The system splits revenue at the quota boundary and applies the rate of each tier to its corresponding portion.

SETTING ENABLED

0 → 48,000	(up to quota)	→ 8.2%	=	3,936.00
48,000 → 50,000	(excess)	→ 9.2%	=	184.00
				4,120.00

Setting disabled: a single rate on the entire sale

The system locates the tier corresponding to the attainment reached prior to the sale and applies that single rate to the whole transaction. Accordingly, a sale of €50,000.00 with no prior revenue has a prior attainment of zero, so the 8.2% tier applies to the whole amount, producing €4,100.00. Across several sales, each is calculated according to the attainment reached before it was recorded, and earlier sales are never recalculated.

VERIFIED CASE — QUOTA €250,000.00 · REVENUE €277,880.25 · TIERS 4% / 7%

250,000.00	× 4%	=	10,000.0000
27,880.25	× 7%	=	1,951.6175
			11,951.62

OPERATIONAL CONSIDERATION

Neither configuration applies the higher rate retroactively to total revenue. Where a client describes a policy under which, once quota is exceeded, the accelerated rate applies to all revenue for the period, that is a third policy which the platform does not implement in either state of the setting. The required model should be confirmed before a response is issued.

OPERATIONAL CONSIDERATION

The setting enabled without an associated quota yields nil. If the accelerator is enabled and the payee has no quota covering the date of the sale, the resulting commission is zero and the corresponding warning is written to the log. Under this configuration, the quota is a prerequisite for earning.

SECTION 7

Quota attainment

$$\text{attainment} = \text{amount achieved} \div \text{target}$$

The result is rounded to four decimal places, with a lower bound of zero and no upper bound: attainment of 120% is represented as 1.20.

The amount achieved is the sum of the sale amounts — gross sales, not commission — for the payee and plan combination whose date falls within the quota period. For quotas measured in units, quantity is accumulated instead of amount.

OPERATIONAL CONSIDERATION

Accumulation covers the entire quota period and is not limited to the current date. The reference date determines which quota applies, but does not bound the accumulation interval. The behaviour resembles a running total to date only because sales with later dates are not usually loaded into the system yet. Backdating a sale, or importing in an order other than chronological, alters the attainment of transactions already processed. The ordinary procedure presents no issue; the criterion is material for retroactive loads and corrections.

FUNCTIONALITY NOT IMPLEMENTED

Weighted averages. Certain compensation designs combine attainment across several sub-periods by means of weighted averages. The platform incorporates no weighting mechanism: attainment is always obtained as a single quotient over one quota period.

SECTION 8

Quotas

A quota is the target amount assigned to a payee, under a plan, over a defined period.

Configuration rules

- The period is defined as a free date range and must fall entirely within the plan period. Partial overlap is rejected.
- The measure may be revenue or units.
- The currency is determined by that of the plan and cannot be modified.

Lifecycle: draft → active → closed

Progression is strictly linear and admits neither reopening nor reversal of closure. State is never derived from dates: only the express actions of activation and closure modify it. A quota whose period has ended remains active until it is closed explicitly.

OPERATIONAL CONSIDERATION

Quotas are immutable once past draft state. To modify a target, the current quota must be closed and a new one created. The interface states this restriction at the point of creation.

OPERATIONAL CONSIDERATION

Overlapping quotas. The system does not prevent several quotas from covering the same date. Where more than one applies, the quota with the narrowest period prevails and, failing that, the most recently created. Monthly quotas within a quarterly plan operate under this criterion, which is a usage convention rather than a parent-child hierarchy modelled in the system.

SECTION 9

Transactions

Transactions represent sales closed with a favourable outcome (*closed-won*). CRM synchronisation guarantees this criterion, as it filters exclusively those deals marked as won. Spreadsheet import and manual entry apply no filter: the system accepts the information as submitted.

Supported sources

SOURCE	PAYEE IDENTIFICATION CRITERION	FILTERS WON
CRM synchronisation	Deal owner, by stored mapping and, failing that, by email address	Yes
Spreadsheet import	Payee code column	No
Manual entry	Express selection of the payee	No

OPERATIONAL CONSIDERATION

Transactions with no payee assigned. A sale received from the CRM whose owner does not correspond to any registered payee is imported nonetheless, with no payee associated: synchronisation is never interrupted and the system does not create payees automatically. Such transactions are listed in the panel's transactions-requiring-attention indicator under the corresponding heading.

Lifecycle: pending → calculated → paid

TRANSITION	CONDITION
→ Pending	Entry of the transaction from any supported source.
Pending → Calculated	Assignment of the corresponding commission credits.
Calculated → Paid	The payment containing it is marked as paid.
Calculated → Pending	Recalculation of credits or reassignment of the payee.
Pending → Cancelled	Voiding of the transaction, with a mandatory reason.
Calculated → Cancelled	The deal was lost in the CRM and the administrator reversed the commission. Applicable to the lost-deal case only; credits are neutralised by offsetting entries and are not deleted.

A transaction in paid state cannot revert to pending. Correction of a commission already settled is performed through the clawback ledger: a debt is recorded against the payee and offset in subsequent settlement cycles (see Section 15). The transaction and its credits are never modified. Only a commission in calculated state, not yet settled, may be reversed; a commission already settled is recovered by way of clawback. The two operations remain deliberately distinct.

DEAL LIFECYCLE IN THE CRM: WON → LOST → WON

A credited deal that moves to lost is detected at the next synchronisation. If its commission is in calculated state only, the panel enables reversal of the commission. If the commission has already been settled, the information is presented for reference only and reversal is not enabled, since reversing a payment already executed would not reflect the reality of the transaction. Instead, recovery on deal loss is triggered automatically and records the corresponding proportional debt. A deal that returns to won is credited again by means of a new transaction; the system never re-credits a commission already settled.

SECTION 10

Measurement period and settlement period

SYSTEM BEHAVIOUR

The two periods are fully independent. A settlement cycle has its own start and end dates, freely determined. No relationship is enforced between a settlement cycle and a quota, so quarterly measurement with monthly settlement is a supported configuration.

A settlement cycle aggregates the transactions whose date falls within the intersection of the cycle's own period and the assignment period, and never within the quota period. The settlement cycle does not recalculate attainment, which was determined earlier, at the point of credit assignment, and always with respect to the quota's own period.

FUNCTIONALITY NOT IMPLEMENTED

Recoverable draws, true-ups and cross-period reconciliation. Models that measure on one calendar and settle on another commonly incorporate recoverable draws and a reconciliation at period close. The platform implements none of these mechanisms: there is no draw, no draw recovery and no reconciliation step.

FUNCTIONALITY NOT IMPLEMENTED

Named frequency (monthly, quarterly or annual) as a formal concept. All periods in the system are defined as free date ranges. Quotas and assignments have no frequency attribute.

SECTION 11

Settlement cycles and payments

A settlement cycle (*pay run*) constitutes the closing of a period for all payees simultaneously. Its scope is organisation-wide: it comprises every active assignment, of every payee, under every plan.

The plan selector in the calculation dialogue serves solely to pre-populate the dates and does not act as a filter on the settlement cycle.

Payments are recalculated; credits are not

Existing payments in calculated state within the period are deleted and rebuilt from the credits in force. Credits were determined earlier, at the point each transaction was processed. To regenerate credits — for example, following a change to the accelerator — the recalculate-credits function must be used on a settlement cycle in draft state, which is a separate and expressly invoked operation.

Lifecycle: draft → approved → paid

- **Approval.** Permitted from draft state only. Each payment in calculated state is approved, excluding payments under dispute.
- **Marking as paid.** Permitted from approved state only. This is an irreversible operation that locks the period, marks credits as consumed and transactions as paid.
- **Reopening.** Permitted from approved state only, and never from paid state. Its scope is always the entire cycle; partial reopening is not supported.

OPERATIONAL CONSIDERATION

Duplicate-payment control. Before a cycle is marked as paid, the system verifies whether any credits have already been consumed by another payment. If any are detected, it blocks the entire cycle, generates the corresponding audit record and lists the conflicting references, rather than failing part-way through the process.

OPERATIONAL CONSIDERATION

Overlapping settlement cycles are permitted. Uniqueness is established on exact dates plus sequence, so the periods 1–31 January and 15 January–15 February may coexist. The effective safeguard against paying the overlapping interval twice is the credit-consumption check, not a period constraint.

IN THE INTERFACE

The payment detail (Payment status) presents a summary comprising payee, plan, period, state and total commission, together with the commission lines, indicating the rule applied, the originating sale, the calculation base and the amount. Expanding a line reveals the plan version, the rate, the trigger conditions and the sequence of adjustments applied. An audit section identifies the author and date of the calculation. Payments of nil value are an expected outcome for payees who are assigned but recorded no sales in the period.

SECTION 12

End-to-end traceability of a sale

Reference scenario: plan *EU Accelerator Q2 2026* (1 April to 30 June, EUR), with one attainment-based rule, tiers of 4% and 7% at the quota boundary, and the accelerator enabled. Payee: Adrian, with a quota of €250,000.00 for the same period. At the time the sale is received, the payee has already accrued €250,000.00 of credited revenue.

CALCULATION APPLICABLE TO THIS SALE

$$27,880.25 \times 7\% = 1,951.6175$$

Had this been the first sale of the quarter, the split would have produced €250,000.00 × 4% + €27,880.25 × 7% = €11,951.6175, the full-quarter figure given in Section 6.

- 01 Receipt of the transaction.** Amount of €27,880.25, with a date falling within the second quarter and the payee identified. State: pending.
- 02 Credit assignment.** The rule trigger is satisfied. The measure is revenue. The table is attainment-based with an accelerator, so the system loads the split context: prior accumulation of €250,000.00 and a target of €250,000.00. The sale falls entirely within the 7% band.
- 03 Settlement cycle calculation** for a period covering the date of the sale. The system identifies every active assignment, intersects its period with that of the cycle, aggregates the transactions and retrieves their credits, generating one payment line per credit.
- 04 Payment generation.** Lines are aggregated into one payment per combination of payee, plan and period, in calculated state.
- 05 Approval and marking as paid.** The system marks each credit as consumed, which precludes its subsequent settlement, and the transactions as paid. The period is locked.

SECTION 13

Functionality not implemented

The concepts listed below are common in the field of variable compensation and are not implemented in the platform. They are set out expressly in order to prevent their being presented as available functionality.

CONCEPT	STATUS
Recoverable draws	Not implemented. There is no draw and no recovery mechanism.
True-ups	Not implemented. There is no reconciliation between a measurement period and its settlements.
Splits across multiple payees (1:N)	Present in the data model only. No effective distribution across multiple payees exists.
Spiffs with distinct behaviour	The designation exists only. Behaviour is that of a multiplier.
Materiality and windfall thresholds	Not implemented.
Formal named frequency	Not implemented. It constitutes metadata with no functional effect.
Weighted averages	Not implemented anywhere in the system.
A second indicator that unlocks a rate	Not implemented. One measure per rule is supported.
Period caps	Not available. Only per-transaction caps apply.
Tier accumulation across a period	The tiered table resets on each transaction. Accumulation is obtained solely through the attainment-based table with an accelerator.

FUNCTIONALITY ADDED IN THIS EDITION

Recovery of commissions already settled. The platform now provides proportional recovery on deal loss, a per-payee ledger with a negative-balance model, and deduction from subsequent settlement cycles, bounded by a cap configurable per plan. See Section 15.

SECTION 14

Material behaviours of the calculation engine

The criteria set out below derive from the functional verifications performed on the engine and describe behaviours implemented deliberately.

- Caps always apply per transaction.
- Trigger conditions are selected from the engine's catalogue — eight fields — with operators determined by data type and validation performed server-side.
- Tiered tables do not accumulate amounts across transactions.
- Attainment accumulates over the entire quota period, so retroactive loads or loads performed out of chronological order alter amounts already processed.
- Quota state never changes automatically: a quota whose period has ended remains active until closed expressly.
- Quotas cannot be modified once past draft state; they must be closed and recreated.
- An accelerator enabled without an associated quota yields nil, with the corresponding warning recorded.
- Settlement cycles are organisation-wide; the plan selector serves only to pre-populate dates.
- Payments of nil value are a correct and expected outcome.
- Modifying a rule does not alter existing credits; credits must be recalculated on a cycle in draft state.
- A payee may be enrolled in several active plans; each sale is credited to every applicable plan.
- The recovery policy is opt-in per plan and inactive by default: without a configured maturation window, no recovery is generated.
- A recovery never modifies the payment it corrects: it records a debt that is offset in subsequent cycles.
- A payee balance may go negative without limit; the cap bounds only the amount withheld in each cycle.
- Terminating a payee freezes the account but does not void a payment already calculated.

- A final settlement must match the balance exactly: amounts above or below are rejected.
- The payee profile (*Rep*) has read access to their own account statement by design.

SECTION 15

Commission recovery (clawback)

Recovery is the mechanism by which the platform corrects a commission already settled. It never modifies the original payment: it records a debt against the payee and offsets it in subsequent settlement cycles. The record is append-only: the sale, its credits and the payment are preserved in their original state, since rewriting the history of a payment that was actually executed is incompatible with the integrity of an accounting record.

15.1 Configuration: an opt-in policy per plan

Configuration is performed under *Plans* → *select a plan* → *Clawback tab*, by means of two optional parameters.

PARAMETER	MEANING	IF LEFT BLANK
Maturation days	The period for which a deal must remain won for the commission to be considered fully earned.	The plan applies no recovery on deal loss.
Cap percentage (0–100)	The maximum proportion of a period's commission that the plan permits to be withheld by way of recovery.	No ceiling: withholding may reach the entire payment.

SYSTEM BEHAVIOUR

The subsystem is inactive by default. Both parameters remain blank on all pre-existing plans, so system behaviour is unchanged until an organisation expressly configures a maturation window.

SYSTEM BEHAVIOUR

A renewed plan inherits the policy in force. A new version of the plan replicates both parameters, since silently losing the recovery policy on renewal would amount to an implicit amnesty for the associated debts.

15.2 Calculation formula

$$\text{recovery} = \frac{\text{commission settled} \times (\text{maturation days} - \text{days active})}{\text{maturation days}} \quad \text{with a lower bound of zero}$$

The formulation reflects two deliberate criteria:

- **Multiplication before division.** Computing the proportion first would introduce rounding before multiplication, with a consequent loss of precision on large commissions. This formulation keeps €900.00 × 60 ÷ 90 at exactly €600.00.
- **Lower bound of zero.** A deal that has survived its maturation window generates no amount to recover: a recovery cannot become an additional payout.

Days active are counted from the favourable close date of the deal to the loss date recorded in the CRM. Cases of origination error — deals that never truly existed — are recovered at 100% rather than proportionally, since no earned time can be recognised on a deal that never existed.

15.3 Cases of application

ORDINARY CASE — DEAL LOST WITHIN THE WINDOW

Plan with 180 maturation days and a 50% cap. Deal closed on 1 February, with a commission of €1,000.00. The CRM records its loss on 1 May, equivalent to 89 days active.

$$1,000.00 \times (180 - 89) \div 180 = 505.5556 \rightarrow \text{debt of } -\text{€}505.5556$$

Next settlement cycle of €2,000.00, 50% cap:

ceiling	= 2,000.00 × 50%	= 1,000.00
withheld	= min(505.5556; 1,000.00)	= 505.5556
net	= 2,000.00 - 505.5556	= 1,494.4444 → balance 0

- **A deal that survives its maturation window.** Loss recorded at 200 days with 180 days of maturation: no entry is generated and the outcome is classified as matured. The ledger records no nil-value entries.
- **The cap prevents full offset of the debt.** Debt of €900.00, payment of €1,000.00 and a 50% cap: the ceiling is €500.00, €500.00 is withheld and the remaining €400.00 is carried forward as outstanding debt. The payee always receives at least the percentage complementary to the cap on the amount earned.

- **Debt exceeding expected earnings.** The balance simply moves further negative, with no lower bound. A lower bound of zero would create an incentive to time a departure against an empty account.
- **A deal credited under two plans.** One entry is recorded per plan, since maturation is a plan-level parameter. Both debits affect the same balance: debt is global per payee and currency, and only the cap operates at plan level.
- **Loss detected across successive synchronisations.** The process is idempotent: a deal that already has its debit does not generate a second entry.
- **Delay between the loss and its detection.** If the deal was lost in March and synchronisation did not run until July, the event date drives the calculation and the entry is recorded in the period currently open. A period that is closed and settled is never reopened to receive a retroactive debt.
- **Commission calculated but not settled.** No debt is created: amounts that never left the organisation are corrected by reversing the commission, not by recording a debt.

15.4 Offset within a settlement cycle

- Debt is global per payee and currency, whereas the cap operates at plan level. A payee enrolled in two plans offsets their single debt against both payments, each bounded by its own cap.
- The order of withholding is deterministic, so two cycles executed on the same data withhold from the same payments and in the same sequence.
- Operations involving different currencies are rejected rather than converted: the platform does not handle exchange rates.

15.5 Permissions

The trigger for recovery on deal loss is system-owned and cannot be invoked manually: it is raised by CRM synchronisation. Consulting the resulting accounting record requires read permission, and recording a manual entry requires adjustment permission (see Section 18).

SECTION 16

Termination management and settlement of outstanding accounts

This section describes the treatment of outstanding amounts when a payee is terminated. Termination freezes the account: earning ceases and the balance no longer moves automatically. Since the freeze alone could leave a debt without visibility, it is accompanied by a dedicated work queue and three express procedures for closing the account.

16.1 Configuration

Termination is recorded under *People* → *select a person* → *Terminate*, stating the effective date. No further configuration is required: the behaviours described below apply automatically.

16.2 System behaviour

SYSTEM BEHAVIOUR

Exclusion of the payee from the calculation engine. From the next calculation onwards, the assignments of a terminated payee are discarded before payment generation. The termination flag resides on the payee record rather than on the accounting record, so the debt is preserved in full, reflected in the balance and in the queue described below.

MATERIAL DETAIL

A payment already calculated is not voided. Termination does not extinguish compensation earned during the employment relationship. The filter prevents the generation of new payments only; an existing residual payment is settled as normal and offsets the outstanding debt, which constitutes the last effective opportunity for recovery.

SYSTEM BEHAVIOUR

Outstanding accounts queue. Available under *Finance* → *Terminated accounts*. It lists every terminated payee whose balance is other than zero, ordered by descending debit amount. Credit balances are likewise included: amounts the organisation still owes a departed payee constitute an open account no less than a debt owed by that payee.

IN THE INTERFACE

The panel reports outstanding accounts first. The count appears in the items-requiring-attention indicator, split between amounts payable (credit balances) and amounts recoverable (debit balances). A single aggregate figure would obscure the nature of the work outstanding, since paying a payee and recovering a debt are distinct procedures.

16.3 Closing an account: three non-interchangeable types

All three types are recorded through the ordinary manual adjustment procedure on the payee's accounting record. The interface offers only the types consistent with the sign of the balance, since offering both directions would permit an amount the organisation owes to be classified as uncollectible, which is not an absorbed loss but non-payment.

BALANCE	TYPE	MEANING	AMOUNT
Debit	External settlement	Amount recovered outside the platform, typically by deduction from the final payroll settlement.	Partial amounts permitted
Debit	Write-off	The organisation absorbs the loss; the debt is classified as uncollectible.	Partial amounts permitted
Credit	Final settlement	Treasury has paid the payee the outstanding amount outside the platform.	Must match the exact balance

Two credit types are provided rather than one generic type because the amount recovered through human resources and the amount absorbed as a loss are distinct economic facts, and the finance function must be able to total each of them without analysing free-text fields.

RATIONALE FOR REQUIRING AN EXACT AMOUNT ON FINAL SETTLEMENT

This type exists in order to extinguish the account and remove it from the outstanding queue. Accordingly, the balance must be a credit — nothing can be settled against a nil balance, and doing so against a debit balance would conceal the debt under a closed-account classification — and the amount must match the balance, since a partial payment leaves a remainder and the account remains outstanding. The platform does not orchestrate instalments; that function belongs to the accounts-payable module of an ERP. A closure is total, or it is not a closure. As the amount is entered manually, the form pre-populates it with the current balance and locks the field; the guarantee, however, resides in the rule rather than in the interface control: the API rejects any non-matching amount with an error, irrespective of browser behaviour.

WORKED EXAMPLES

Terminated payee with a credit balance of +€500.00

Final settlement of €500.00 → balance 0.0000; account leaves the queue

Final settlement of €600.00 → rejected; nothing recorded, balance + €500.00

Final settlement of €300.00 → rejected; partial closures are not permitted

Terminated payee with a debit balance of -€250.00

Write-off of €250.00 → balance 0

Write-off of €150.00 → accepted; remainder of -€100.00

16.4 Delimitation of the platform's scope

The platform freezes and records; it does not perform collection activity.

Deduction from the final payroll settlement, referral to a collections process, or the pursuit of legal action fall to the human resources, finance and legal functions, using information the platform does not hold. Its role is to make it impossible for an open account to go unnoticed, and to preserve the decision taken by the finance function.

SECTION 17

Account statement (ledger)

The account statement is the view of the recovery subsystem available to the payee, found under *People* → *select a person* → *Clawback tab*. It presents two calculation expressions, the current balance, and every entry that has moved it.

17.1 The two calculation expressions

Cash flow of the settled cycle

`commissions - withheld = amount received for the period`

Balance movement

`opening balance + amount amortised = balance carried forward in that cycle`

Both expressions refer to a payment already executed. All amounts are calculated server-side and none is recalculated in the browser: if the settlement states a withholding of €500.00, that is the amount actually withheld.

OPERATIONAL CONSIDERATION

The cap percentage may deliberately be left blank. Where the plans that generated payments to the payee in that cycle carry different caps, no single applicable percentage exists, so the field remains empty. Stating an arbitrary value in a document that explains an individual's compensation would be inaccurate.

17.2 Current balance and historical balance

FIGURE	DEFINITION	WHEN IT CHANGES
Current balance	The sum of all entries in the payee's accounting record as at today.	On every entry, including those added after the last settled cycle.
Balance carried forward in the cycle	The amount outstanding at the close of that payment.	Never: it is historical information.

The two figures are presented in separate fields and the screen gives precedence to the current balance. Where they differ, the reason is stated: "Movements were recorded after this settlement cycle (–€333.33), so the current balance is

–€833.33."

OPERATIONAL CONSIDERATION

Any figure relating to the settled cycle is shown as a dash when absent, and never as a zero. A zero would assert that the payee has neither earned nor received any amount, when the actual position is that no settlement cycle has yet been closed against that balance.

17.3 The ledger detail

The record is append-only and is presented in reverse chronological order, with three redundant signals distinguishing system-generated entries from manual ones: icon, colour band, and the sign and colour of the amount, since colour alone is not accessible to all users. The entry types are as follows.

ENTRY TYPE	SIGN	AUTHORISED TO RECORD
Recovery debit	–	The calculation engine only
Recovery credit applied	+	The calculation engine only
Debt forgiveness	+	Authorised user: a business decision to forgive an actual debt
Manual bonus	+	Authorised user
Data-correction debit	–	Authorised user: erroneous data inflated a payment
Data-correction credit	+	Authorised user: neutralises an entry arising from a technical fault
External settlement	+	Authorised user: debt recovered outside the platform
Write-off	+	Authorised user: loss absorbed by the organisation
Final settlement	–	Authorised user: amount paid to a terminated payee

SYSTEM BEHAVIOUR

Debt forgiveness and data correction are distinct concepts, and the distinction is not presentational. Forgiveness is a business decision: a user with the requisite authority relinquishes an actual debt. Using it to correct an erroneous import would represent to the finance leadership that the organisation had forgiven amounts it never earned.

17.4 Manual adjustments

- The author of an entry is taken from the authenticated user and never from the request: an adjustment whose authorship could be determined by the caller does not constitute an auditable record.
- Justification is mandatory and is enforced in the domain, not solely in the form.

- The record is append-only: errors are corrected by a counter-entry, and both movements remain visible.
- On save, the screen retrieves the information from the server rather than updating the balance locally.

SECTION 18

Permissions and roles

The system defines four roles, mapped to explicit permissions. The interface applies a uniform criterion throughout the product: unauthorised actions are hidden and never presented in a disabled state. The screen displays only the actions available to the user, and the API enforces the restriction irrespective of what the browser has rendered.

ROLE	SCOPE
Tenant administrator	Full scope, including subscription, general settings and integrations.
Commissions manager	Full operational scope: payees, plans, quotas, assignments, transactions, credits, payments, accounting record, imports and reports, excluding subscription, general settings and integrations.
Manager	Read access: payees, quotas, assignments and accounting record.
Payee (<i>Rep</i>)	Read access: payees, assignments, quotas and accounting record.

RATIONALE FOR PAYEE ACCESS TO THE ACCOUNTING RECORD

Transparency is a differentiating attribute of the platform: the payee can consult their own balance and the detail of the movements that have changed it. A deduction the payee cannot verify erodes confidence in the compensation system. The reporting manager holds the same access because they must be able to explain a reduced payment to their team.

OPERATIONAL CONSIDERATION

Read permission on the accounting record is not scoped at row level: any user holding it may consult the accounting record of any payee within their organisation. Isolation between organisations is guaranteed; per-payee scoping is not implemented in the current version.

SECTION 19

HubSpot integration

HubSpot is the system of reference for sales. The platform connects to the organisation's HubSpot account, retrieves deals closed with a favourable outcome, converts them into transactions, and keeps the information synchronised, including cases in which a deal is lost after its commission has been settled.

19.1 Establishing the connection

The connection is established once, under *Settings* → *Integrations* → *HubSpot*. The platform uses HubSpot's standard authorisation flow (OAuth): on initiating the connection, the user is redirected to HubSpot to authenticate and authorise access, and HubSpot returns the authorisation without any credential being transmitted to the platform. From that point, the platform can securely query the account's deals, and the organisation may revoke access from HubSpot at any time.

19.2 Scope of synchronisation

SYSTEM BEHAVIOUR

The platform retrieves deals closed with a favourable outcome (*closed-won*) exclusively. The filter is applied by HubSpot according to its own classification, so a deal lost from the outset, or one that remains open, generates no record in the platform. A deal must reach the won state in order to generate commission, since without a settled commission there is no amount capable of subsequent recovery.

OPERATIONAL CONSIDERATION

Synchronisation neither creates payees automatically nor halts. If the owner of a deal in HubSpot does not correspond to any payee registered in the platform, the deal is imported nonetheless but remains without a payee assigned, and is listed in the panel's transactions-requiring-attention indicator for manual resolution.

19.3 Identifying the payee of a deal

Every deal recorded in HubSpot has an assigned owner. The platform links that owner to a payee by two criteria, applied in the following order:

1. **Stored mapping.** If the HubSpot owner is already linked to a payee in the platform, that link is applied directly.
2. **Email address match.** In the absence of a stored mapping, the platform locates a payee whose email address matches that of the deal owner exactly.

If neither criterion identifies a payee, the deal remains unassigned as described above. Consequently, the email address registered in the platform must match that held in HubSpot for the link to be established automatically.

19.4 Mapping HubSpot states to platform behaviour

Synchronisation runs periodically and queries the current state of each deal. The platform does not take a point-in-time snapshot: it re-evaluates deals on every run, which enables it to detect changes of state.

SITUATION IN HUBSPOT	PLATFORM BEHAVIOUR
A deal is marked as won	A transaction is created with the close date and enters the ordinary commission calculation flow.
A won deal is marked as lost, commission not yet settled	The situation is detected at the next synchronisation and the panel enables reversal of the commission.
A won deal is marked as lost, commission already settled	Recovery is triggered automatically and the corresponding proportional debt is recorded (see Section 15). Reversal is not enabled, as the amount has already been disbursed.
A lost deal returns to won	It is credited again by means of a new transaction; the prior history remains unmodified.

19.5 Treatment of the close date

The close date of the deal in HubSpot is the determining data point, and the platform reads it at two distinct moments:

- When the deal is marked as won, that date is fixed as the transaction date and determines the start of commission accrual.
- When the deal is marked as lost, the platform reads the close date again — which at that point corresponds to the date of loss — and uses it to calculate proportional recovery, according to the number of days active.

OPERATIONAL CONSIDERATION

On closing a deal as lost, HubSpot may overwrite the close date with the current date. Where a loss must be recorded with a specific date — for example, to reflect the point at which the contract was actually terminated — the close date in HubSpot should be verified, since the exact recovery calculation depends on it. Use of the calendar picker is recommended in order to avoid date-format ambiguity.

SUMMARY

The HubSpot connection is established once. From that point, the platform retrieves deals closed with a favourable outcome, links them to registered payees by email address, and keeps the information current — including the most demanding case: the loss of a deal whose commission has already been settled, and the consequent recovery of the amount. The platform reads from HubSpot and never writes back to it.

CLOSING STATEMENT

Scope of the platform

Wasnie is the system of record for variable compensation: it determines the amounts earned, settles them by period, and — when a deal is lost or a payee departs — corrects the account by means of entries that preserve the history in full. It is neither a financial institution nor a payroll system: its role is to provide a correct and auditable figure for use in downstream processes.
